**METHODS FOR FILTERING AIR FOR A GAS TURBINE SYSTEM**

10

15

**Related Application**

This application claims priority under 35 U.S.C. §119(e) to U.S. provisional application serial number 60/230,138, filed on September 5, 2000, incorporated by reference herein.

20

**Field of the Invention**

The present invention relates to a filter arrangement and filtration method. More specifically, it concerns an arrangement for filtering particulate material from a gas flow stream, for example, an air stream. The invention also concerns a method for achieving the desirable removal of particulate material from such a gas flow stream.

25

### **Background of the Invention**

The present invention is an on-going development of Donaldson Company Inc., of Minneapolis, Minnesota, the assignee of the present invention. The disclosure concerns  
5 continuing technology development related, in part, to the subjects characterized in U.S. Patents: B2 4,720,292; Des 416,308; 5,613,992; 4,020,783; and 5,112,372. Each of the patents identified in the previous sentence is also owned by Donaldson, Inc., of Minneapolis, Minnesota; and, the complete disclosure of each is incorporated herein by reference.

The invention also relates to polymer materials can be manufactured with improved  
10 environmental stability to heat, humidity, reactive materials and mechanical stress. Such materials can be used in the formation of fine fibers such as microfibers and nanofiber materials with improved stability and strength. As the size of fiber is reduced the survivability of the materials is increasingly more of a problem. Such fine fibers are useful in a variety of applications. In one application, filter structures can be prepared using this  
15 fine fiber technology. The invention relates to polymers, polymeric composition, fiber, filters, filter constructions, and methods of filtering. Applications of the invention particularly concern filtering of particles from fluid streams, for example from air streams and liquid (e.g. non-aqueous and aqueous) streams. The techniques described concern structures having one or more layers of fine fibers in the filter media. The compositions and  
20 fiber sizes are selected for a combination of properties and survivability.

The invention relates to polymeric compositions with improved properties that can be used in a variety of applications including the formation of fibers, fine fiber, microfibers, nanofibers, fiber webs, fibrous mats, permeable structures such as membranes, coatings or films. The polymeric materials of the invention are compositions that have physical  
25 properties that permit the polymeric material, in a variety of physical shapes or forms, to have resistance to the degradative effects of humidity, heat, air flow, chemicals and mechanical stress or impact. In making non-woven filter media, a variety of materials have been used including fiberglass, metal, ceramics and a wide range of polymeric compositions. A variety of techniques have been used for the manufacture of small diameter fine fiber such  
30 as micro- and nanofibers. One method involves passing the material through a fine capillary or opening either as a melted material or in a solution that is subsequently evaporated. Fibers

can also be formed by using "spinnerets" typical for the manufacture of synthetic fiber such as nylon. Electrostatic spinning is also known. Such techniques involve the use of a hypodermic needle, nozzle, capillary or movable emitter. These structures provide liquid solutions of the polymer that are then attracted to a collection zone by a high voltage electrostatic field. As the materials are pulled from the emitter and accelerate through the electrostatic zone, the fiber becomes very thin and can be formed in a fiber structure by solvent evaporation.

As more demanding applications are envisioned for filtration media, significantly improved materials are required to withstand the rigors of high temperature 100°F to 250°F (and up to 300°F), high humidity 10% to 90% up to 100% RH, high flow rates of both gas and liquid, and filtering micron and submicron particulates (ranging from about 0.01 to over 10 microns) and removing both abrasive and non-abrasive and reactive and non-reactive particulate from the fluid stream.

Accordingly, a substantial need exists for polymeric materials, micro- and nanofiber materials and filter structures that provide improved properties for cleaning air intake into gas turbine systems at higher temperatures, higher humidities and high flow rates.

### **Summary of the Invention**

Herein, general methods for the cleaning of an air intake stream in a gas turbine system are provided. The methods include utilizing preferred filter media. In general, the preferred media concern utilization, within an air filter, of barrier media, typically pleated media, and fine fibers, to advantage.

The filter media includes at least a micro- or nanofiber web layer in combination with a substrate material in a mechanically stable filter structure. These layers together provide excellent filtering, high particle capture, efficiency at minimum flow restriction when a fluid such as a gas or liquid passes through the filter media. The substrate can be positioned in the fluid stream upstream, downstream or in an internal layer. A variety of industries have directed substantial attention in recent years to the use of filtration media for filtration, i.e. the removal of unwanted particles from a fluid such as gas or liquid. The common filtration process removes particulate from fluids including an air stream or other gaseous stream or from a liquid stream such as a hydraulic fluid, lubricant oil, fuel, water stream or other fluids.

Such filtration processes require the mechanical strength, chemical and physical stability of the microfiber and the substrate materials. The filter media can be exposed to a broad range of temperature conditions, humidity, mechanical vibration and shock and both reactive and non-reactive, abrasive or non-abrasive particulates entrained in the fluid flow. Further, the filtration media often require the self-cleaning ability of exposing the filter media to a reverse pressure pulse (a short reversal of fluid flow to remove surface coating of particulate) or other cleaning mechanism that can remove entrained particulate from the surface of the filter media. Such reverse cleaning can result in substantially improved (i.e.) reduced pressure drop after the pulse cleaning. Particle capture efficiency typically is not improved after pulse cleaning, however pulse cleaning will reduce pressure drop, saving energy for filtration operation. Such filters can be removed for service and cleaned in aqueous or non-aqueous cleaning compositions. Such media are often manufactured by spinning fine fiber and then forming an interlocking web of microfiber on a porous substrate. In the spinning process the fiber can form physical bonds between fibers to interlock the fiber mat into a integrated layer. Such a material can then be fabricated into the desired filter format such as cartridges, flat disks, canisters, panels, bags and pouches. Within such structures, the media can be substantially pleated, rolled or otherwise positioned on support structures.

#### **Brief Description of the Drawings**

FIGURE 1 depicts a typical electrostatic emitter driven apparatus for production of the fine fibers of the invention.

FIGURE 2 shows the apparatus used to introduce fine fiber onto filter substrate into the fine fiber forming technology shown in Figure 1.

FIGURE 3 is a depiction of the typical internal structure of a support material and a separate depiction of the fine fiber material of the invention compared to small, i.e. 2 and 5 micron particulate materials.

FIGURES 4 through 11 are analytical ESCA spectra relating to Example 13.

FIGURE 12 shows the stability of the 0.23 and 0.45 microfiber material of the invention from Example 5.

FIGURES 13 through 16 show the improved temperature and humidity stability of the materials of Examples 5 and 6 when compared to unmodified nylon copolymer solvent soluble polyamide.

FIGURES 17 through 20 demonstrate that the blend of two copolymers, a nylon homopolymer and a nylon copolymer, once heat treated and combined with additives form a single component material that does not display distinguishable characteristics of two separate polymer materials, but appears to be a crosslinked or otherwise chemically joined single phase.

FIGURE 21 is a schematic cross-sectional view of a gas turbine air intake filtration system, utilized in the methods of this disclosure; and

FIGURE 22 is a schematic cross-sectional view of another gas turbine intake filtration system, similar to the system of Figure 21 but smaller, utilized in the methods of this disclosure.

### **Detailed Description of the Invention**

The invention provides an improved polymeric material. This polymer has improved physical and chemical stability. The polymer fine fiber (microfiber and nanofiber) can be fashioned into useful product formats. Nanofiber is a fiber with diameter less than 200 nanometer or 0.2 micron. Microfiber is a fiber with diameter larger than 0.2 micron, but not larger than 10 microns. This fine fiber can be made in the form of an improved multi-layer microfiltration media structure. The fine fiber layers of the invention comprise a random distribution of fine fibers which can be bonded to form an interlocking net. Filtration performance is obtained largely as a result of the fine fiber barrier to the passage of particulate. Structural properties of stiffness, strength, pleatability are provided by the substrate to which the fine fiber adhered. The fine fiber interlocking networks have as important characteristics, fine fibers in the form of microfibers or nanofibers and relatively small spaces between the fibers. Such spaces typically range, between fibers, of about 0.01 to about 25 microns or often about 0.1 to about 10 microns. The filter products comprising a fine fiber layer and a cellulosic layer are thin with a choice of appropriate substrate. The fine fiber adds less than a micron in thickness to the overall fine fiber plus substrate filter media. In service, the filters can stop incident particulate from passing through the fine fiber layer

and can attain substantial surface loadings of trapped particles. The particles comprising dust or other incident particulates rapidly form a dust cake on the fine fiber surface and maintains high initial and overall efficiency of particulate removal. Even with relatively fine contaminants having a particle size of about 0.01 to about 1 micron, the filter media comprising the fine fiber has a very high dust capacity.

The polymer materials as disclosed herein have substantially improved resistance to the undesirable effects of heat, humidity, high flow rates, reverse pulse cleaning, operational abrasion, submicron particulates, cleaning of filters in use and other demanding conditions. The improved microfiber and nanofiber performance is a result of the improved character of the polymeric materials forming the microfiber or nanofiber. Further, the filter media of the invention using the improved polymeric materials of the invention provides a number of advantageous features including higher efficiency, lower flow restriction, high durability (stress related or environmentally related) in the presence of abrasive particulates and a smooth outer surface free of loose fibers or fibrils. The overall structure of the filter materials provides an overall thinner media allowing improved media area per unit volume, reduced velocity through the media, improved media efficiency and reduced flow restrictions.

A preferred mode of the invention is a polymer blend comprising a first polymer and a second, but different polymer (differing in polymer type, molecular weight or physical property) that is conditioned or treated at elevated temperature. The polymer blend can be reacted and formed into a single chemical specie or can be physically combined into a blended composition by an annealing process. Annealing implies a physical change, like crystallinity, stress relaxation or orientation. Preferred materials are chemically reacted into a single polymeric specie such that a Differential Scanning Calorimeter analysis reveals a single polymeric material. Such a material, when combined with a preferred additive material, can form a surface coating of the additive on the microfiber that provides oleophobicity, hydrophobicity or other associated improved stability when contacted with high temperature, high humidity and difficult operating conditions. The fine fiber of the class of materials can have a diameter of 2 microns to less than 0.01 micron. Such microfibers can have a smooth surface comprising a discrete layer of the additive material or an outer coating of the additive material that is partly solubilized or alloyed in the polymer

surface, or both. Preferred materials for use in the blended polymeric systems include nylon 6; nylon 66; nylon 6-10; nylon (6-66-610) copolymers and other linear generally aliphatic nylon compositions. A preferred nylon copolymer resin (SVP-651) was analyzed for molecular weight by the end group titration. (J.E. Walz and G.B. Taylor, determination of the molecular weight of nylon, Anal. Chem. Vol. 19, Number 7, pp 448-450 (1947). A number average molecular weight ( $W_n$ ) was between 21,500 and 24,800. The composition was estimated by the phase diagram of melt temperature of three component nylon, nylon 6 about 45%, nylon 66 about 20% and nylon 610 about 25%. (Page 286, Nylon Plastics Handbook, Melvin Kohan ed. Hanser Publisher, New York (1995)).

Reported physical properties of SVP 651 resin are:

<u>-Property</u>	<u>ASTM Method</u>	<u>Units</u>	<u>Typical Value</u>
Specific Gravity	D-792	--	1.08
Water Absorption (24 hr immersion)	D-570	%	2.5
Hardness	D-240	Shore D	65
Melting Point	DSC	°C(°F)	154 (309)
Tensile Strength @ Yield	D-638	MPa (kpsi)	50 (7.3)
Elongation at Break	D-638	%	350
Flexural Modulus	D-790	MPa (kpsi)	180 (26)
Volume Resistivity	D-257	ohm-cm	$10^{12}$

A polyvinylalcohol having a hydrolysis degree of from 87 to 99.9+% can be used in such polymer systems. These are preferably cross linked. And they are most preferably crosslinked and combined with substantial quantities of the oleophobic and hydrophobic additive materials.

Another preferred mode of the invention involves a single polymeric material combined with an additive composition to improve fiber lifetime or operational properties. The preferred polymers useful in this aspect of the invention include nylon polymers, polyvinylidene chloride polymers, polyvinylidene fluoride polymers, polyvinylalcohol polymers and, in particular, those listed materials when combined with strongly oleophobic

and hydrophobic additives that can result in a microfiber or nanofiber with the additive materials formed in a coating on the fine fiber surface. Again, blends of similar polymers such as a blend of similar nylons, similar polyvinylchloride polymers, blends of polyvinylidene chloride polymers are useful in this invention. Further, polymeric blends or alloys of differing polymers are also contemplated by the invention. In this regard, compatible mixtures of polymers are useful in forming the microfiber materials of the invention. Additive composition such a fluoro-surfactant, a nonionic surfactant, low molecular weight resins (e.g.) tertiary butylphenol resin having a molecular weight of less than about 3000 can be used. The resin is characterized by oligomeric bonding between phenol nuclei in the absence of methylene bridging groups. The positions of the hydroxyl and the tertiary butyl group can be randomly positioned around the rings. Bonding between phenolic nuclei always occurs next to hydroxyl group, not randomly. Similarly, the polymeric material can be combined with an alcohol soluble non-linear polymerized resin formed from bis-phenol A. Such material is similar to the tertiary butylphenol resin described above in that it is formed using oligomeric bonds that directly connect aromatic ring to aromatic ring in the absence of any bridging groups such as alkylene or methylene groups.

A particularly preferred material of the invention comprises a microfiber material having a dimension of about 0.0001 to 5 microns. The most preferred fiber size range between 0.001 to 0.2 micron. Such fibers with the preferred size provide excellent filter activity, ease of back pulse cleaning and other aspects. The highly preferred polymer systems of the invention have adhering characteristic such that when contacted with a cellulosic substrate adheres to the substrate with sufficient strength such that it is securely bonded to the substrate and can resist the delaminating effects of a reverse pulse cleaning technique and other mechanical stresses. In such a mode, the polymer material must stay attached to the substrate while undergoing a pulse clean input that is substantially equal to the typical filtration conditions except in a reverse direction across the filter structure. Such adhesion can arise from solvent effects of fiber formation as the fiber is contacted with the substrate or the post treatment of the fiber on the substrate with heat or pressure. However, polymer characteristics appear to play an important role in determining adhesion, such as specific chemical interactions like hydrogen bonding, contact between polymer and substrate

occurring above or below Tg, and the polymer formulation including additives. Polymers plasticized with solvent or steam at the time of adhesion can have increased adhesion.

An important aspect of the invention is the utility of such microfiber or nanofiber materials formed into a filter structure. In such a structure, the fine fiber materials of the invention are formed on and adhered to a filter substrate. Natural fiber and synthetic fiber substrates, like spun bonded fabrics, non-woven fabrics of synthetic fiber and non-wovens made from the blends of cellulose, synthetic and glass fibers, non-woven and woven glass fabrics, plastic screen like materials both extruded and hole punched, UF and MF membranes of organic polymers can be used. Sheet-like substrate or cellulosic non-woven web can then be formed into a filter structure that is placed in a fluid stream including an air stream or liquid stream for the purpose of removing suspended or entrained particulate from that stream. The shape and structure of the filter material is up to the design engineer. One important parameter of the filter elements after formation is its resistance to the effects of heat, humidity or both. One aspect of the filter media of the invention is a test of the ability of the filter media to survive immersion in warm water for a significant period of time. The immersion test can provide valuable information regarding the ability of the fine fiber to survive hot humid conditions and to survive the cleaning of the filter element in aqueous solutions that can contain substantial proportions of strong cleaning surfactants and strong alkalinity materials. Preferably, the fine fiber materials of the invention can survive immersion in hot water while retaining at least 50% of the fine fiber formed on the surface of the substrate. Retention of at least 50% of the fine fiber can maintain substantial fiber efficiency without loss of filtration capacity or increased back pressure. Most preferably retaining at least 75%.

The fine fibers that comprise the micro- or nanofiber containing layer of the invention can be fiber and can have a diameter of about 0.001 to 5 microns, 0.001 to 2 microns, 0.05 to 0.5 micron, preferably 0.01 to 0.2 micron. The thickness of the typical fine fiber filtration layer ranges from about 0.1 to 3 micron (about 1 to 100 times) the fiber diameter with a basis weight ranging from about 0.01 to 240 micrograms-cm<sup>-2</sup>.

Fluid streams such as air and gas streams often carry particulate material therein. The removal of some or all of the particulate material from the fluid stream is needed. For example, air intake streams to the cabins of motorized vehicles, air in computer disk drives,

HVAC air, clean room ventilation and applications using filter bags, barrier fabrics, woven materials, air to engines for motorized vehicles, or to power generation equipment; gas streams directed to gas turbines; and, air streams to various combustion furnaces, often include particulate material therein. In the case of cabin air filters it is desirable to remove the particulate matter for comfort of the passengers and/or for aesthetics. With respect to air and gas intake streams to engines, gas turbines and combustion furnaces, it is desirable to remove the particulate material because particulate can cause substantial damage to the internal workings to the various mechanisms involved. In other instances, production gases or off gases from industrial processes or engines may contain particulate material therein. Before such gases can be, or should be, discharged through various downstream equipment to the atmosphere, it may be desirable to obtain a substantial removal of particulate material from those streams.

A general understanding of some of the basic principles and problems of air filter design can be understood by consideration of the following types of filter media: surface loading media; and, depth media. Each of these types of media has been well studied, and each has been widely utilized. Certain principles relating to them are described, for example, in U.S. Patent Nos. 5,082,476; 5,238,474; and 5,364,456. The complete disclosures of these three patents are incorporated herein by reference.

The "lifetime" of a filter is typically defined according to a selected limiting pressure drop across the filter. The pressure buildup across the filter defines the lifetime at a defined level for that application or design. Since this buildup of pressure is a result of load, for systems of equal efficiency a longer life is typically directly associated with higher capacity. Efficiency is the propensity of the media to trap, rather than pass, particulates. It should be apparent that typically the more efficient a filter media is at removing particulates from a gas flow stream, in general the more rapidly the filter media will approach the "lifetime" pressure differential (assuming other variables to be held constant). In this application the term "unchanged for filtration purposes" refers to maintaining sufficient efficiency to remove particulate from the fluid stream as is necessary for the selected application.

Polymeric materials have been fabricated in non-woven and woven fabrics, fibers and microfibers. The polymeric material provides the physical properties required for product stability. These materials should not change significantly in dimension, suffer reduced

molecular weight, become less flexible or subject to stress cracking or physically deteriorate in the presence of sunlight, humidity, high temperatures or other negative environmental effects. The invention relates to an improved polymeric material that can maintain physical properties in the face of incident electromagnetic radiation such as environmental light, heat,  
5 humidity and other physical challenges.

Polymer materials that can be used in the polymeric compositions of the invention include both addition polymer and condensation polymer materials such as polyolefin, polyacetal, polyamide, polyester, cellulose ether and ester, polyalkylene sulfide, polyarylene oxide, polysulfone, modified polysulfone polymers and mixtures thereof. Preferred materials  
10 that fall within these generic classes include polyethylene, polypropylene, poly(vinylchloride), polymethylmethacrylate (and other acrylic resins), polystyrene, and copolymers thereof (including ABA type block copolymers), poly(vinylidene fluoride), poly(vinylidene chloride), polyvinylalcohol in various degrees of hydrolysis (87% to 99.5%) in crosslinked and non-crosslinked forms. Preferred addition polymers tend to be glassy (a  
15 T<sub>g</sub> greater than room temperature). This is the case for polyvinylchloride and polymethylmethacrylate, polystyrene polymer compositions or alloys or low in crystallinity for polyvinylidene fluoride and polyvinylalcohol materials. One class of polyamide condensation polymers are nylon materials. The term "nylon" is a generic name for all long chain synthetic polyamides. Typically, nylon nomenclature includes a series of numbers  
20 such as in nylon-6,6 which indicates that the starting materials are a C<sub>6</sub> diamine and a C<sub>6</sub> diacid (the first digit indicating a C<sub>6</sub> diamine and the second digit indicating a C<sub>6</sub> dicarboxylic acid compound). Another nylon can be made by the polycondensation of epsilon caprolactam in the presence of a small amount of water. This reaction forms a nylon-6 (made from a cyclic lactam - also known as epsilon-aminocaproic acid) that is a linear  
25 polyamide. Further, nylon copolymers are also contemplated. Copolymers can be made by combining various diamine compounds, various diacid compounds and various cyclic lactam structures in a reaction mixture and then forming the nylon with randomly positioned monomeric materials in a polyamide structure. For example, a nylon 6,6-6,10 material is a nylon manufactured from hexamethylene diamine and a C<sub>6</sub> and a C<sub>10</sub> blend of diacids. A  
30 nylon 6-6,6-6,10 is a nylon manufactured by copolymerization of epsilonaminocaproic acid, hexamethylene diamine and a blend of a C<sub>6</sub> and a C<sub>10</sub> diacid material.

Block copolymers are also useful in the process of this invention. With such copolymers the choice of solvent swelling agent is important. The selected solvent is such that both blocks were soluble in the solvent. One example is a ABA (styrene-EP-styrene) or AB (styrene-EP) polymer in methylene chloride solvent. If one component is not soluble in the solvent, it will form a gel. Examples of such block copolymers are Kraton<sup>®</sup> type of styrene-b-butadiene and styrene-b-hydrogenated butadiene(ethylene propylene), Pebax<sup>®</sup> type of e-caprolactam-b-ethylene oxide, Sympatex<sup>®</sup> polyester-b-ethylene oxide and polyurethanes of ethylene oxide and isocyanates.

Addition polymers like polyvinylidene fluoride, syndiotactic polystyrene, copolymer of vinylidene fluoride and hexafluoropropylene, polyvinyl alcohol, polyvinyl acetate, amorphous addition polymers, such as poly(acrylonitrile) and its copolymers with acrylic acid and methacrylates, polystyrene, poly(vinyl chloride) and its various copolymers, poly(methyl methacrylate) and its various copolymers, can be solution spun with relative ease because they are soluble at low pressures and temperatures. However, highly crystalline polymer like polyethylene and polypropylene require high temperature, high pressure solvent if they are to be solution spun. Therefore, solution spinning of the polyethylene and polypropylene is very difficult. Electrostatic solution spinning is one method of making nanofibers and microfiber.

We have also found a substantial advantage to forming polymeric compositions comprising two or more polymeric materials in polymer admixture, alloy format or in a crosslinked chemically bonded structure. We believe such polymer compositions improve physical properties by changing polymer attributes such as improving polymer chain flexibility or chain mobility, increasing overall molecular weight and providing reinforcement through the formation of networks of polymeric materials.

In one embodiment of this concept, two related polymer materials can be blended for beneficial properties. For example, a high molecular weight polyvinylchloride can be blended with a low molecular weight polyvinylchloride. Similarly, a high molecular weight nylon material can be blended with a low molecular weight nylon material. Further, differing species of a general polymeric genus can be blended. For example, a high molecular weight styrene material can be blended with a low molecular weight, high impact polystyrene. A Nylon-6 material can be blended with a nylon copolymer such as a Nylon-6; 6,6; 6,10

copolymer. Further, a polyvinylalcohol having a low degree of hydrolysis such as a 87% hydrolyzed polyvinylalcohol can be blended with a fully or superhydrolyzed polyvinylalcohol having a degree of hydrolysis between 98 and 99.9% and higher. All of these materials in admixture can be crosslinked using appropriate crosslinking mechanisms.

5 Nylons can be crosslinked using crosslinking agents that are reactive with the nitrogen atom in the amide linkage. Polyvinylalcohol materials can be crosslinked using hydroxyl reactive materials such as monoaldehydes, such as formaldehyde, ureas, melamine-formaldehyde resin and its analogues, boric acids and other inorganic compounds. dialdehydes, diacids, urethanes, epoxies and other known crosslinking agents. Crosslinking technology is a well  
10 known and understood phenomenon in which a crosslinking reagent reacts and forms covalent bonds between polymer chains to substantially improve molecular weight, chemical resistance, overall strength and resistance to mechanical degradation.

We have found that additive materials can significantly improve the properties of the polymer materials in the form of a fine fiber. The resistance to the effects of heat, humidity,  
15 impact, mechanical stress and other negative environmental effect can be substantially improved by the presence of additive materials. We have found that while processing the microfiber materials of the invention, that the additive materials can improve the oleophobic character, the hydrophobic character and can appear to aid in improving the chemical stability of the materials. We believe that the fine fibers of the invention in the form of a  
20 microfiber are improved by the presence of these oleophobic and hydrophobic additives as these additives form a protective layer coating, ablative surface or penetrate the surface to some depth to improve the nature of the polymeric material. We believe the important characteristics of these materials are the presence of a strongly hydrophobic group that can preferably also have oleophobic character. Strongly hydrophobic groups include  
25 fluorocarbon groups, hydrophobic hydrocarbon surfactants or blocks and substantially hydrocarbon oligomeric compositions. These materials are manufactured in compositions that have a portion of the molecule that tends to be compatible with the polymer material affording typically a physical bond or association with the polymer while the strongly hydrophobic or oleophobic group, as a result of the association of the additive with the  
30 polymer, forms a protective surface layer that resides on the surface or becomes alloyed with or mixed with the polymer surface layers. For 0.2-micron fiber with 10% additive level, the

surface thickness is calculated to be around 50 Å, if the additive has migrated toward the surface. Migration is believed to occur due to the incompatible nature of the oleophobic or hydrophobic groups in the bulk material. A 50 Å thickness appears to be reasonable thickness for protective coating. For 0.05-micron diameter fiber, 50 Å thickness corresponds to 20% mass. For 2 microns thickness fiber, 50 Å thickness corresponds to 2% mass.

Preferably the additive materials are used at an amount of about 2 to 25 wt.%. Oligomeric additives that can be used in combination with the polymer materials of the invention include oligomers having a molecular weight of about 500 to about 5000, preferably about 500 to about 3000 including fluoro-chemicals, nonionic surfactants and low molecular weight resins or oligomers. Fluoro-organic wetting agents useful in this invention are organic molecules represented by the formula

wherein  $R_f$  is a fluoroaliphatic radical and G is a group which contains at least one hydrophilic group such as cationic, anionic, nonionic, or amphoteric groups. Nonionic materials are preferred.  $R_f$  is a fluorinated, monovalent, aliphatic organic radical containing at least two carbon atoms. Preferably, it is a saturated perfluoroaliphatic monovalent organic radical. However, hydrogen or chlorine atoms can be present as substituents on the skeletal chain. While radicals containing a large number of carbon atoms may function adequately, compounds containing not more than about 20 carbon atoms are preferred since large radicals usually represent a less efficient utilization of fluorine than is possible with shorter skeletal chains. Preferably,  $R_f$  contains about 2 to 8 carbon atoms.

The cationic groups that are usable in the fluoro-organic agents employed in this invention may include an amine or a quaternary ammonium cationic group which can be oxygen-free (e.g.,  $-NH_2$ ) or oxygen-containing (e.g., amine oxides). Such amine and quaternary ammonium cationic hydrophilic groups can have formulas such as  $-NH_2$ ,  $-(NH_3)X$ ,  $-(NH(R^2)_2)X$ ,  $-(NH(R^2)_3)X$ , or  $-N(R^2)_2 \rightarrow O$ , where x is an anionic counterion such as halide, hydroxide, sulfate, bisulfate, or carboxylate,  $R^2$  is H or  $C_{1-18}$  alkyl group, and each  $R^2$  can be the same as or different from other  $R^2$  groups. Preferably,  $R^2$  is H or a  $C_{1-16}$  alkyl group and X is halide, hydroxide, or bisulfate.

The anionic groups which are usable in the fluoro-organic wetting agents employed in this invention include groups which by ionization can become radicals of anions. The anionic groups may have formulas such as -COOM, -SO<sub>3</sub>M, -OSO<sub>3</sub>M, -PO<sub>3</sub>HM, -OPO<sub>3</sub>M<sub>2</sub>, or -OPO<sub>3</sub>HM, where M is H, a metal ion, (NR<sup>1</sup><sub>4</sub>)<sup>+</sup>, or (SR<sup>1</sup><sub>4</sub>)<sup>+</sup>, where  
5 each R<sup>1</sup> is independently H or substituted or unsubstituted C<sub>1</sub>-C<sub>6</sub> alkyl. Preferably M is Na<sup>+</sup> or K<sup>+</sup>. The preferred anionic groups of the fluoro-organo wetting agents used in this invention have the formula -COOM or -SO<sub>3</sub>M. Included within the group of anionic fluoro-organic wetting agents are anionic polymeric materials typically manufactured from ethylenically unsaturated carboxylic mono- and diacid monomers having pendent  
10 fluorocarbon groups appended thereto. Such materials include surfactants obtained from 3M Corporation known as FC-430 and FC-431.

The amphoteric groups which are usable in the fluoro-organic wetting agent employed in this invention include groups which contain at least one cationic group as defined above and at least one anionic group as defined above.

15 The nonionic groups which are usable in the fluoro-organic wetting agents employed in this invention include groups which are hydrophilic but which under pH conditions of normal agronomic use are not ionized. The nonionic groups may have formulas such as -O(CH<sub>2</sub>CH<sub>2</sub>)<sub>x</sub>OH where x is greater than 1, -SO<sub>2</sub>NH<sub>2</sub>, -SO<sub>2</sub>NHCH<sub>2</sub>CH<sub>2</sub>OH, -SO<sub>2</sub>N(CH<sub>2</sub>CH<sub>2</sub>H)<sub>2</sub>, -CONH<sub>2</sub>, -CONHCH<sub>2</sub>CH<sub>2</sub>OH, or -  
20 CON(CH<sub>2</sub>CH<sub>2</sub>OH)<sub>2</sub>. Examples of such materials include materials of the following structure:

25 wherein n is 2 to 8 and m is 0 to 20.

Other fluoro-organic wetting agents include those cationic fluorochemicals described, for example in U.S. Patent Nos. 2,764,602; 2,764,603; 3,147,064 and 4,069,158. Such amphoteric fluoro-organic wetting agents include those amphoteric fluorochemicals described, for example, in U.S. Patent Nos. 2,764,602; 4,042,522; 4,069,158; 4,069,244;  
30 4,090,967; 4,161,590 and 4,161,602. Such anionic fluoro-organic wetting agents include

those anionic fluorochemicals described, for example, in U.S. Patent Nos. 2,803,656; 3,255,131; 3,450,755 and 4,090,967.

Examples of such materials are duPont Zonyl FSN and duPont Zonyl FSO nonionic surfactants. Another aspect of additives that can be used in the polymers of the invention include low molecular weight fluorocarbon acrylate materials such as 3M's Scotchgard material having the general structure:

wherein X is -F or -CF<sub>3</sub> and n is 1 to 7.

Further, nonionic hydrocarbon surfactants including lower alcohol ethoxylates, fatty acid ethoxylates, nonylphenol ethoxylates, etc. can also be used as additive materials for the invention. Examples of these materials include Triton X-100 and Triton N-101.

A useful material for use as an additive material in the compositions of the invention are tertiary butylphenol oligomers. Such materials tend to be relatively low molecular weight aromatic phenolic resins. Such resins are phenolic polymers prepared by enzymatic oxidative coupling. The absence of methylene bridges result in unique chemical and physical stability. These phenolic resins can be crosslinked with various amines and epoxies and are compatible with a variety of polymer materials. These materials are generally exemplified by the following structural formulas which are characterized by phenolic materials in a repeating motif in the absence of methylene bridge groups having phenolic and aromatic groups.

5

wherein n is 2 to 20. Examples of these phenolic materials include Enzo-BPA, Enzo-BPA/phenol, Enzo-TBP, Enzo-COP and other related phenolics were obtained from Enzymol International Inc., Columbus, Ohio.

10 It should be understood that an extremely wide variety of fibrous filter media exist for different applications. The durable nanofibers and microfibers described in this invention can be added to any of the media. The fibers described in this invention can also be used to

substitute for fiber components of these existing media giving the significant advantage of improved performance (improved efficiency and/or reduced pressure drop) due to their small diameter, while exhibiting greater durability.

Polymer nanofibers and microfibers are known, however their use has been very limited due to their fragility to mechanical stresses, and their susceptibility to chemical degradation due to their very high surface area to volume ratio. The fibers described in this invention address these limitations and will therefore be usable in a very wide variety of filtration, textile, membrane and other diverse applications.

### Detailed Description Of Certain Drawings

The microfiber or nanofiber of the unit can be formed by the electrostatic spinning process. A suitable apparatus for forming the fiber is illustrated in Figure 1. This apparatus includes a reservoir 80 in which the fine fiber forming polymer solution is contained, a pump 81 and a rotary type emitting device or emitter 40 to which the polymeric solution is pumped. The emitter 40 generally consists of a rotating union 41, a rotating portion 42 including a plurality of offset holes 44 and a shaft 43 connecting the forward facing portion and the rotating union. The rotating union 41 provides for introduction of the polymer solution to the forward facing portion 42 through the hollow shaft 43. The holes 44 are spaced around the periphery of the forward facing portion 42. Alternatively, the rotating portion 42 can be immersed into a reservoir of polymer fed by reservoir 80 and pump 81. The rotating portion 42 then obtains polymer solution from the reservoir and as it rotates in the electrostatic field, a droplet of the solution is accelerated by the electrostatic field toward the collecting media 70 as discussed below.

Facing the emitter 40, but spaced apart therefrom, is a substantially planar grid 60 upon which the collecting media 70 (i.e. substrate or combined substrate) is positioned. Air can be drawn through the grid. The collecting media 70 is passed around rollers 71 and 72 which are positioned adjacent opposite ends of grid 60. A high voltage electrostatic potential is maintained between emitter 40 and grid 60 by means of a suitable electrostatic voltage source 61 and connections 62 and 63 which connect respectively to the grid 60 and emitter 40.

In use, the polymer solution is pumped to the rotating union 41 or reservoir from reservoir 80. The forward facing portion 42 rotates while liquid exits from holes 44, or is picked up from a reservoir, and moves from the outer edge of the emitter toward collecting media 70 positioned on grid 60. Specifically, the electrostatic potential between grid 60 and the emitter 40 imparts a charge to the material which cause liquid to be emitted therefrom as thin fibers which are drawn toward grid 60 where they arrive and are collected on substrate 12 or an efficiency layer 14. In the case of the polymer in solution, solvent is evaporated off the fibers during their flight to the grid 60; therefore, the fibers arrive at the substrate 12 or efficiency layer 14. The fine fibers bond to the substrate fibers first encountered at the grid 60. Electrostatic field strength is selected to ensure that the polymer material as it is accelerated from the emitter to the collecting media 70, the acceleration is sufficient to render the material into a very thin microfiber or nanofiber structure. Increasing or slowing the advance rate of the collecting media can deposit more or less emitted fibers on the forming media, thereby allowing control of the thickness of each layer deposited thereon. The rotating portion 42 can have a variety of beneficial positions. The rotating portion 42 can be placed in a plane of rotation such that the plane is perpendicular to the surface of the collecting media 70 or positioned at any arbitrary angle. The rotating media can be positioned parallel to or slightly offset from parallel orientation. Figure 2 is a general schematic diagram of a process and apparatus for forming a layer of fine fiber on a sheet-like substrate or media. In Figure 2, the sheet-like substrate is unwound at station 20. The sheet-like substrate 20a is then directed to a splicing station 21 wherein multiple lengths of the substrate can be spliced for continuous operation. The continuous length of sheet-like substrate is directed to a fine fiber technology station 22 comprising the spinning technology of Figure 1 wherein a spinning device forms the fine fiber and lays the fine fiber in a filtering layer on the sheet-like substrate. After the fine fiber layer is formed on the sheet-like substrate in the formation zone 22, the fine fiber layer and substrate are directed to a heat treatment station 23 for appropriate processing. The sheet-like substrate and fine fiber layer is then tested in an efficiency monitor 24 (see U.S. Pat. No. 5,203,201 which is expressly incorporated by reference herein for process and monitoring purposes) and nipped if necessary at a nip station 25. The sheet-like substrate and fiber layer is then steered to the

appropriate winding station to be wound onto the appropriate spindle for further processing  
26 and 27.

Figure 3 is a scanning electromicrograph image showing the relationship of typical  
dust particles having a diameter of about 2 and about 5 microns with respect to the sizes of  
5 pores in typical cellulose media and in the typical fine fiber structures. In Figure 3A, the 2  
micron particle 31 and the 5 micron particle 32 is shown in a cellulosic media 33 with pore  
sizes that are shown to be quite a bit larger than the typical particle diameters. In sharp  
contrast, in Figure 3B, the 2 micron particle 31 appears to be approximately equal to or  
greater than the typical openings between the fibers in the fiber web 35 while the 5 micron  
10 particle 32 appears to be larger than any of the openings in the fine fiber web 35.

The foregoing general description of the various aspects of the polymeric materials of  
the invention, the fine fiber materials of the invention including both microfibers and  
nanofibers and the construction of useful filter structures from the fine fiber materials of the  
invention provides an understanding of the general technological principles of the operation  
15 of the invention. The following specific exemplary materials are examples of materials that  
can be used in the formation of the fine fiber materials of the invention and the following  
materials disclose a best mode. The following exemplary materials were manufactured with  
the following characteristics and process conditions in mind. Electrospinning small diameter  
fiber less than 10 micron is obtained using an electrostatic force from a strong electric field  
20 acting as a pulling force to stretch a polymer jet into a very fine filament. A polymer melt can  
be used in the electrospinning process, however, fibers smaller than 1 micron are best made  
from polymer solution. As the polymer mass is drawn down to smaller diameter, solvent  
evaporates and contributes to the reduction of fiber size. Choice of solvent is critical for  
several reasons. If solvent dries too quickly, then fibers tends to be flat and large in diameter.  
25 If the solvent dries too slowly, solvent will redissolve the formed fibers. Therefore matching  
drying rate and fiber formation is critical. At high production rates, large quantities of  
exhaust air flow helps to prevent a flammable atmosphere, and to reduce the risk of fire. A  
solvent that is not combustible is helpful. In a production environment the processing  
equipment will require occasional cleaning. Safe low toxicity solvents minimize worker  
30 exposure to hazardous chemicals. Electrostatic spinning can be done at a flow rate of 1.5

ml/min per emitter, a target distance of 8 inches, an emitter voltage of 88 kV, an emitter rpm of 200 and a relative humidity of 45%.

The choice of polymer system is important for a given application. For pulse cleaning application, an extremely thin layer of microfiber can help to minimize pressure loss and provide an outer surface for particle capture and release. A thin layer of fibers of less than 2-micron diameter, preferably less than 0.3-micron diameter is preferred. Good adhesion between microfiber or nanofiber and substrates upon which the microfibers or nanofibers are deposited is important. When filters are made of composites of substrate and thin layer of micro- and nanofibers, such composite makes an excellent filter medium for self-cleaning application. Cleaning the surface by back pulsing repeatedly rejuvenates the filter medium. As a great force is exerted on the surface, fine fiber with poor adhesion to substrates can delaminate upon a back pulse that passes from the interior of a filter through a substrate to the micro fiber. Therefore, good cohesion between micro fibers and adhesion between substrate fibers and electrospun fibers is critical for successful use.

Products that meet the above requirements can be obtained using fibers made from different polymer materials. Small fibers with good adhesion properties can be made from such polymers like polyvinylidene chloride, poly vinyl alcohol and polymers and copolymers comprising various nylons such as nylon 6, nylon 4,6; nylon 6,6; nylon 6,10 and copolymers thereof. Excellent fibers can be made from PVDF, but to make sufficiently small fiber diameters requires chlorinated solvents. Nylon 6, Nylon 66 and Nylon 6,10 can be electrospun. But, solvents such as formic acid, m-cresol, tri-fluoro ethanol, hexafluoro isopropanol are either difficult to handle or very expensive. Preferred solvents include water, ethanol, isopropanol, acetone and N-methyl pyrrolidone due to their low toxicity. Polymers compatible with such solvent systems have been extensively evaluated. We have found that fibers made from PVC, PVDC, polystyrene, polyacrylonitrile, PMMA, PVDF require additional adhesion means to attain structural properties. We also found that when polymers are dissolved in water, ethanol, isopropanol, acetone, methanol and mixtures thereof and successfully made into fibers, they have excellent adhesion to the substrate, thereby making an excellent filter medium for self-cleaning application. Self-cleaning via back air pulse or twist is useful when filter medium is used for very high dust concentration. Fibers from alcohol soluble polyamides and poly(vinyl alcohol)s have been used successfully in such

applications. Examples of alcohol soluble polyamides include Macromelt 6238, 6239, and 6900 from Henkel, Elvamide 8061 and 8063 from duPont and SVP 637 and 651 from Shakespeare Monofilament Company. Another group of alcohol soluble polyamide is type 8 nylon, alkoxy alkyl modifies nylon 66 (Ref. Page 447, Nylon Plastics handbook, Melvin Kohan ed. Hanser Publisher, New York, 1995). Examples of poly(vinyl alcohol) include PVA-217, 224 from Kuraray, Japan and Vinol 540 from Air Products and Chemical Company. We have found that filters can be exposed to extremes in environmental conditions. Filters in Saudi Arabian desert can be exposed to temperature as high as 150 F° or higher. Filters installed in Indonesia or Gulf Coast of US can be exposed high humidity above 90 % RH and high temperature of 100 F°. Or, they can be exposed to rain. We have found that filters used under the hood of mobile equipment like cars, trucks, buses, tractors, and construction equipment can be exposed to high temperature (+200°F), high relative humidity and other chemical environment. We have developed test methods to evaluate survivability of microfiber systems under harsh conditions. Soaking the filter media samples in hot water (140 F°) for 5 minutes or exposure to high humidity, high temperature and air flow.

Single stage, self cleaning air filter systems are known. One such system, commercially available, is the Donaldson GDX™ Pulse Cleaning Filter System available from Donaldson Company, Inc., Minneapolis, Minnesota. In Figure 21, a schematic, cross-sectional, depiction of a Donaldson GDX™ Pulse Cleaning Filter System 20 is presented. The system of Figure 21 is not prior art, in that it utilizes certain preferred media formulations in its methods for filtering the air intake stream. Other than certain preferred media formulations utilized in the system of Figure 21, the structure in the system of Figure 21 is described in U.S. Patent 6,123,751, which is incorporated by reference herein, and which is commercially available from Donaldson.

Referring to Figure 21, the system 220 includes a chamber 221 having an air inlet side 222 and an air outlet side 223. Air enters the chamber 221 through a plurality of vertically spaced inlet hoods 226 positioned along the air inlet side 222. The inlet hoods 226 function to protect internal filters of the system 220 from the effects of rain, snow and sun. Also, the inlet hoods 226 are configured such that air entering the inlet hoods 226 is first directed in an upward direction indicated by arrow 227, and then deflected by deflector plates

228 in a downward direction indicated by arrow 229. The initial upward movement of air causes some particulate material and moisture from the air stream to settle or accumulate on lower regions 230 of the inlet hoods 226. The subsequent downward movement of air forces dust within the chamber 221 downward toward a dust collection hopper 232 located at the bottom of the chamber 221.

The chamber 221 of the system 220 is divided into upstream and downstream volumes 234 and 236 by a partition 238. The upstream volume 234 generally represents the "dirty air section" of the air cleaner system 220, while the downstream volume generally represents the "clean air section" of the system 220. The partition 238 defines a plurality of apertures 240 for allowing air to flow from the upstream volume 234 to the downstream volume 236. Each aperture 240 is covered by an air filter 242 or filter cartridge located in the upstream volume 234 of the chamber. The filters 242 are arranged and configured such that air flowing from the upstream volume 234 to the downstream volume 236 passes through the filters 242 prior to passing through the apertures 40.

For the particular filter arrangement shown, each air filter 242 includes a pair of filter elements. For example, each air filter 242 includes a cylindrical element 244 and, a somewhat truncated, conical, element 246. Each truncated, conical element 246 includes one end having a major diameter and another end having a minor diameter. The cylindrical element 244 and the truncated, conical element 246 of each filter 242 are co-axially aligned and connected end-to-end with the minor diameter end of each conical element 246 being secured to one of the cylindrical elements 244 in a sealed manner. The major diameter end of each truncated, conical element 246 is secured to the partition 238 such that an annular seal is formed around its corresponding aperture 240. Each filter 242 is generally co-axially aligned with respect to its corresponding aperture 240 and has a longitudinal axis that is generally horizontal.

Each of the filter elements 242, 246 includes a media pack 260, 262 forming a tubular construction 264, 266 and defining an open filter interior 268, 270 within the construction. The open filter interior 268, 270 is also a clean air plenum. Preferably, each media pack 260, 262 is pleated and comprises a composite of a substrate at least partially covered by a layer of fine fibers. Preferred formulations for media composites are described below.

In general, during filtering, air is directed from the upstream volume 234 radially through the air filters 242 into interior volumes 268, 270 (clean air plenums) of the filters 242. After being filtered, the air flows from the interior volumes 248 through the partition 238, via apertures 240, into the downstream clean air volume 236. The clean air is then  
5 drawn out from the downstream volume 236, through apertures 250, into a gas turbine intake, not shown.

Each aperture 240 of the partition 238 includes a pulse jet air cleaner 252 mounted in the downstream volume 236. Periodically, the pulse jet air cleaner 252 is operated to direct a pulse jet of air, shown at arrows 272, backwardly through the associated air filter 242, i.e.  
10 from the interior volume 268, 270 of the filter element outwardly to shake or otherwise dislodge particular material trapped in or on the filter media of the air filter 242. The pulse jet air cleaners 252 can be sequentially operated from the top to the bottom of the chamber 221 to eventually direct the dust particulate material blown from the filters into the lower hopper 232, for removal.

Arrangements such as those shown in Figure 21 may be rather large. Filter pairs used in such arrangements commonly include cylindrical filters that are about 26 inches long and about 12.75 inches in diameter, and truncated conical filters that are about 26 inches long, about 12.75 inches in minor diameter, and about 17.5 inches in major diameter. Such arrangements might be used, for example, for filtering intake air to a gas turbine system  
20 having an air flow demand on the order of 8000 to 1.2 million cubic feet per minute (cfm).

In Figure 22, another air intake filtration system for a gas turbine is illustrated. Other than preferred media formulations, the system shown in Figure 22 is commercially available as the Donaldson GDX™ Self-Cleaning Air Filter available from Donaldson Company. In Figure 22, a schematic, cross-sectional, depiction of a Donaldson GDX™ Self Cleaning Air  
25 Filter 120 is presented. The system of Figure 22 is not prior art, in that it utilizes certain preferred media formulations in its methods for filtering the air intake stream. The system 120 of Figure 22 is similar to the system 20 of Figure 21, except that the system 120 is depicted as a smaller, more compact unit.

In Figure 22, the system 120 includes a chamber 121 having an air inlet side 122 and  
30 an air outlet side 123. Air enters the chamber 121 through an inlet hood 126 positioned along the air inlet side 122. The inlet hood 126 helps to direct air entering the inlet hood 126 in an

upward direction indicated by arrow 127, and then deflect by deflector plate 128 in a downward direction indicated by arrow 129. The downward movement of air forces dust within the chamber 21 downward toward a dust collection hopper 132 located at the bottom of the chamber 121.

5 As with system 10 of Figure 21, the chamber 121 of the system 120 is divided into upstream and downstream volumes 134 and 136 by a partition 138. The upstream volume 134 represents the "dirty air section" of the air cleaner system 120, while the downstream volume generally represents the "clean air section" of the system 120. The partition 138 defines a plurality of apertures 140 for allowing air to flow from the upstream volume 134 to the downstream volume 136. Each aperture 140 is covered by an air filter 142 or filter  
10 cartridge located in the upstream volume 134 of the chamber. The filters 142 are arranged and configured such that air flowing from the upstream volume 134 to the downstream volume 136 passes through the filters 142 prior to passing through the apertures 140.

Each air filter 142 includes a pair of filter elements. For example, each air filter 142  
15 includes a cylindrical element 144 and, a truncated, conical, element 146. Each truncated, conical element 146 includes one end having a major diameter and another end having a minor diameter. The cylindrical element 144 and the truncated, conical element 146 of each filter 142 are co-axially aligned and connected end-to-end with the minor diameter end of each conical element 146 being secured to one of the cylindrical elements 144 in a sealed  
20 manner. The major diameter end of each truncated, conical element 146 is secured to the partition 138 such that an annular seal is formed around its corresponding aperture 140. Each filter 142 is generally co-axially aligned with respect to its corresponding aperture 140 and has a longitudinal axis that is generally horizontal.

Each of the filter elements 144, 146 includes a media pack 160, 162 forming a tubular  
25 construction 164, 166 and defining an open filter interior 168, 170 within the construction. Preferably, each media pack 160, 162 is pleated and comprises a composite of a substrate at least partially covered by a layer of fine fibers. Preferred formulations for media composites are described below.

In general, during filtering, air is directed from the upstream volume 134 radially  
30 through the air filters 142 into interior volumes 168, 170 (clean air plenums) of the filters 142. After being filtered, the air flows from the interior volumes 168, 170 through the

partition 138, via apertures 140, into the downstream clean air volume 136. The clean air is then drawn out from the downstream volume 136, through apertures 150, into a gas turbine intake, not shown.

Each aperture 140 of the partition 138 includes a pulse jet air cleaner 152 mounted in the downstream volume 136. Periodically, the pulse jet air cleaner 152 is operated to direct a pulse jet of air backwardly, shown at arrows 172, through the associated air filter 142, i.e. from the interior volume 168, 170 of the filter element outwardly to shake or otherwise dislodge particular material trapped in or on the filter media of the air filter 142. The pulse jet air cleaners 152 can be sequentially operated from the top to the bottom of the chamber 121 to eventually direct the dust particulate material blown from the filters into the lower hopper 132, for removal.

#### **Preferred Media Formulations**

In gas turbine air intake systems, during operation, the ambient temperature or equipment operating temperature can sometimes reach at least 140°F, and often is in the range of 150-350°F. Further, the humidity can sometimes be high, in the range of at least 75% RH, often 85 to 99+% RH. The temperature and/or humidity may adversely affect the operating efficiency of the filter element. Constructing the filter media 260, 262 in the form of a composite of a barrier media treated with preferred formulations of fine fiber can improve the performance of the filter elements over prior art filter elements that are not constructed from such media composites.

A fine fiber filter structure includes a bi-layer or multi-layer structure wherein the filter contains one or more fine fiber layers combined with or separated by one or more synthetic, cellulosic or blended webs. Another preferred motif is a structure including fine fiber in a matrix or blend of other fibers.

We believe important characteristics of the fiber and microfiber layers in the filter structure relate to temperature resistance, humidity or moisture resistance and solvent resistance, particularly when the microfiber is contacted with humidity, moisture or a solvent at elevated temperatures. Further, a second important property of the materials of the invention relates to the adhesion of the material to a substrate structure. The microfiber layer adhesion is an important characteristic of the filter material such that the material can be

manufactured without delaminating the microfiber layer from the substrate, the microfiber layer plus substrate can be processed into a filter structure including pleats, rolled materials and other structures without significant delamination. We have found that the heating step of the manufacturing process wherein the temperature is raised to a temperature at or near but just below melt temperature of one polymer material, typically lower than the lowest melt temperature substantially improves the adhesion of the fibers to each other and the substrate. At or above the melt temperature, the fine fiber can lose its fibrous structure. It is also critical to control heating rate. If the fiber is exposed to its crystallization temperature for extended period of time, it is also possible to lose fibrous structure. Careful heat treatment also improved polymer properties that result from the formation of the exterior additive layers as additive materials migrate to the surface and expose hydrophobic or oleophobic groups on the fiber surface.

While the temperature of the filter, under normal operating characteristics is the same as the temperature of the ambient air passing through the filter, the filter can be exposed to high temperature. The filter can be exposed to high heat during time of restricted air flow, time when the operations stop and the equipment temperature is hot or in time of abnormal operation. The criteria for performance is that the material be capable of surviving intact various operating filter temperatures, i.e. a temperature of 140°F, 160°F, 270°F, 300°F for a period of time of 1 hour or 3 hours, depending on end use, while retaining 30%, 50%, 80% or 90% of filter efficiency. An alternative criteria for performances that the material is capable of surviving intact at various operating filter temperatures, i.e. temperatures of 140°F, 160°F, 270°F, 300°F, for a period of time of 1 hours or 3 hours depending on end use, while retaining, depending on end use, 30%, 50%, 80% or 90% of effective fine fibers in a filter layer. Survival at these temperatures is important at low humidity, high humidity, and in water saturated air. The microfiber and filter material of the invention are deemed moisture resistant where the material can survive immersion at a temperature of greater than 160°F while maintaining efficiency for a time greater than about 5 minutes. Similarly, solvent resistance in the microfiber material and the filter material of the invention is obtained from a material that can survive contact with a solvent such as ethanol, a hydrocarbon, a hydraulic fluid, or an aromatic solvent for a period of time greater than about 5 minutes at 70°F while maintaining 50% efficiency.

The fine fiber materials of the invention can be used in a variety of filter applications including pulse clean and non-pulse cleaned filters for dust collection, gas turbines and engine air intake or induction systems; gas turbine intake or induction systems, heavy duty engine intake or induction systems, light vehicle engine intake or induction systems; Zee  
5 filter; vehicle cabin air; off road vehicle cabin air, disk drive air, photocopier-toner removal; HVAC filters in both commercial or residential filtration applications.

Paper filter elements are widely used forms of surface loading media. In general, paper elements comprise dense mats of cellulose, synthetic or other fibers oriented across a gas stream carrying particulate material. The paper is generally constructed to be permeable  
10 to the gas flow, and to also have a sufficiently fine pore size and appropriate porosity to inhibit the passage of particles greater than a selected size therethrough. As the gases (fluids) pass through the filter paper, the upstream side of the filter paper operates through diffusion and interception to capture and retain selected sized particles from the gas (fluid) stream. The particles are collected as a dust cake on the upstream side of the filter paper. In time, the  
15 dust cake also begins to operate as a filter, increasing efficiency. This is sometimes referred to as "seasoning," i.e. development of an efficiency greater than initial efficiency.

A simple filter design such as that described above is subject to at least two types of problems. First, a relatively simple flaw, i.e. rupture of the paper, results in failure of the system. Secondly, particulate material rapidly builds up on the upstream side of the filter, as  
20 a thin dust cake or layer, increasing the pressure drop. Various methods have been applied to increase the "lifetime" of surface-loaded filter systems, such as paper filters. One method is to provide the media in a pleated construction, so that the surface area of media encountered by the gas flow stream is increased relative to a flat, non-pleated construction. While this increases filter lifetime, it is still substantially limited. For this reason, surface loaded media  
25 has primarily found use in applications wherein relatively low velocities through the filter media are involved, generally not higher than about 20-30 feet per minute and typically on the order of about 10 feet per minute or less. The term "velocity" in this context is the average velocity through the media (i.e. flow volume per media area).

In general, as air flow velocity is increased through a pleated paper media, filter life is  
30 decreased by a factor proportional to the square of the velocity. Thus, when a pleated paper, surface loaded, filter system is used as a particulate filter for a system that requires

substantial flows of air, a relatively large surface area for the filter media is needed. For example, a typical cylindrical pleated paper filter element of an over-the-highway diesel truck will be about 9-15 inches in diameter and about 12-24 inches long, with pleats about 1-2 inches deep. Thus, the filtering surface area of media (one side) is typically 30 to 300 square feet.

In many applications, especially those involving relatively high flow rates, an alternative type of filter media, sometimes generally referred to as "depth" media, is used. A typical depth media comprises a relatively thick tangle of fibrous material. Depth media is generally defined in terms of its porosity, density or percent solids content. For example, a 2-3% solidity media would be a depth media mat of fibers arranged such that approximately 2-3% of the overall volume comprises fibrous materials (solids), the remainder being air or gas space.

Another useful parameter for defining depth media is fiber diameter. If percent solidity is held constant, but fiber diameter (size) is reduced, pore size or interfiber space is reduced; i.e. the filter becomes more efficient and will more effectively trap smaller particles.

A typical conventional depth media filter is a deep, relatively constant (or uniform) density, media, i.e. a system in which the solidity of the depth media remains substantially constant throughout its thickness. By "substantially constant" in this context, it is meant that only relatively minor fluctuations in density, if any, are found throughout the depth of the media. Such fluctuations, for example, may result from a slight compression of an outer engaged surface, by a container in which the filter media is positioned.

Gradient density depth media arrangements have been developed. some such arrangements are described, for example, in U.S. Patent Nos. 4,082,476; 5,238,474; and 5,364,456. In general, a depth media arrangement can be designed to provide "loading" of particulate materials substantially throughout its volume or depth. Thus, such arrangements can be designed to load with a higher amount of particulate material, relative to surface loaded systems, when full filter lifetime is reached. However, in general the tradeoff for such arrangements has been efficiency, since, for substantial loading, a relatively low solidity media is desired. Gradient density systems such as those in the patents referred to above, have been designed to provide for substantial efficiency and longer life. In some instances, surface loading media is utilized as a "polish" filter in such arrangements.

A filter media construction according to the present invention includes a first layer of permeable coarse fibrous media or substrate having a first surface. A first layer of fine fiber media is secured to the first surface of the first layer of permeable coarse fibrous media.

Preferably the first layer of permeable coarse fibrous material comprises fibers having an average diameter of at least 10 microns, typically and preferably about 12 (or 14) to 30 microns. Also preferably the first layer of permeable coarse fibrous material comprises a media having a basis weight of no greater than about 200 grams/meter<sup>2</sup>, preferably about 0.50 to 150 g/m<sup>2</sup>, and most preferably at least 8 g/m<sup>2</sup>. Preferably the first layer of permeable coarse fibrous media is at least 0.0005 inch (12 microns) thick, and typically and preferably is about 0.001 to 0.030 inch (25-800 microns) thick.

In preferred arrangements, the first layer of permeable coarse fibrous material comprises a material which, if evaluated separately from a remainder of the construction by the Frazier permeability test, would exhibit a permeability of at least 1 meter(s)/min, and typically and preferably about 2-900 meters/min. Herein when reference is made to efficiency, unless otherwise specified, reference is meant to efficiency when measured according to ASTM-1215-89, with 0.78 $\mu$  monodisperse polystyrene spherical particles, at 20 fpm (6.1 meters/min) as described herein.

Preferably the layer of fine fiber material secured to the first surface of the layer of permeable coarse fibrous media is a layer of nano- and microfiber media wherein the fibers have average fiber diameters of no greater than about 2 microns, generally and preferably no greater than about 1 micron, and typically and preferably have fiber diameters smaller than 0.5 micron and within the range of about 0.05 to 0.5 micron. Also, preferably the first layer of fine fiber material secured to the first surface of the first layer of permeable coarse fibrous material has an overall thickness that is no greater than about 30 microns, more preferably no more than 20 microns, most preferably no greater than about 10 microns, and typically and preferably that is within a thickness of about 1-8 times (and more preferably no more than 5 times) the fine fiber average diameter of the layer.

Certain preferred arrangements according to the present invention include filter media as generally defined, in an overall filter construction. Some preferred arrangements for such use comprise the media arranged in a cylindrical, pleated configuration with the pleats extending generally longitudinally, i.e. in the same direction as a longitudinal axis of the

cylindrical pattern. For such arrangements, the media may be imbedded in end caps, as with conventional filters. Such arrangements may include upstream liners and downstream liners if desired, for typical conventional purposes.

In some applications, media according to the present invention may be used in conjunction with other types of media, for example conventional media, to improve overall filtering performance or lifetime. For example, media according to the present invention may be laminated to conventional media, be utilized in stack arrangements; or be incorporated (an integral feature) into media structures including one or more regions of conventional media. It may be used upstream of such media, for good load; and/or, it may be used downstream from conventional media, as a high efficiency polishing filter.

Certain arrangements according to the present invention may also be utilized in liquid filter systems, i.e. wherein the particulate material to be filtered is carried in a liquid. Also, certain arrangements according to the present invention may be used in mist collectors, for example arrangements for filtering fine mists from air.

According to the present invention, methods are provided for filtering. The methods generally involve utilization of media as described to advantage, for filtering. As will be seen from the descriptions and examples below, media according to the present invention can be specifically configured and constructed to provide relatively long life in relatively efficient systems, to advantage.

Various filter designs are shown in patents disclosing and claiming various aspects of filter structure and structures used with the filter materials. Engel et al., U.S. Patent No. 4,720,292, disclose a radial seal design for a filter assembly having a generally cylindrical filter element design, the filter element being sealed by a relatively soft, rubber-like end cap having a cylindrical, radially inwardly facing surface. Kahlbaugh et al., U.S. Patent No. 5,082,476, disclose a filter design using a depth media comprising a foam substrate with pleated components combined with the microfiber materials of the invention. Stifelman et al., U.S. Patent No. 5,104,537, relate to a filter structure useful for filtering liquid media. Liquid is entrained into the filter housing, passes through the exterior of the filter into an interior annular core and then returns to active use in the structure. Such filters are highly useful for filtering hydraulic fluids. Engel et al., U.S. Patent No. 5,613,992, show a typical diesel engine air intake filter structure. The structure obtains air from the external aspect of

the housing that may or may not contain entrained moisture. The air passes through the filter while the moisture can pass to the bottom of the housing and can drain from the housing.

Gillingham et al., U.S. Patent No. 5,820,646, disclose a Z filter structure that uses a specific pleated filter design involving plugged passages that require a fluid stream to pass through at least one layer of filter media in a "Z" shaped path to obtain proper filtering performance.

The filter media formed into the pleated Z shaped format can contain the fine fiber media of the invention. Glen et al., U.S. Patent No. 5,853,442, disclose a bag house structure having filter elements that can contain the fine fiber structures of the invention. Berkhoel et al., U.S. Patent No. 5,954,849, show a dust collector structure useful in processing typically air having large dust loads to filter dust from an air stream after processing a workpiece generates a significant dust load in an environmental air. Lastly, Gillingham, U.S. Design Patent No. 425,189, discloses a panel filter using the Z filter design.

### **Experimental**

The following materials were produced using the following electrospin process conditions.

The following materials were spun using either a rotating emitter system or a capillary needle system. Both were found to produce substantially the same fibrous materials.

The flow rate was 1.5 mil/min per emitter, a target distance of 8 inches, an emitter voltage of 88 kV, a relative humidity of 45%, and for the rotating emitter an rpm of 35.

### **Example 1:**

#### **Effect of Fiber Size**

Fine fiber samples were prepared from a copolymer of nylon 6, 66, 610 nylon copolymer resin (SVP-651) was analyzed for molecular weight by the end group titration. (J.E. Walz and G.B. Taylor, determination of the molecular weight of nylon, Anal. Chem. Vol. 19, Number 7, pp 448-450 (1947). Number average molecular weight was between 21,500 and 24,800. The composition was estimated by the phase diagram of melt temperature of three component nylon, nylon 6 about 45%, nylon 66 about 20% and nylon

610 about 25%. (Page 286, Nylon Plastics Handbook, Melvin Kohan ed. Hanser Publisher, New York (1995)). Reported physical properties of SVP 651 resin are:

	<u>Property</u>	<u>ASTM Method</u>	<u>Units</u>	<u>Typical Value</u>
5	Specific Gravity	D-792	--	1.08
	Water Absorption (24 hr immersion)	D-570	%	2.5
	Hardness	D-240	Shore D	65
	Melting Point	DSC	°C(°F)	154 (309)
10	Tensile Strength @ Yield	D-638	MPa (kpsi)	50 (7.3)
	Elongation at Break	D-638	%	350
	Flexural Modulus	D-790	MPa (kpsi)	180 (26)
15	Volume Resistivity	D-257	ohm-cm	10 <sup>12</sup>

to produce fiber of 0.23 and 0.45 micron in diameter. Samples were soaked in room temperature water, air-dried and its efficiency was measured. Bigger fiber takes longer time to degrade and the level of degradation was less as can be seen in the plot of Figure 12. While wishing not to be limited by certain theory, it appears that smaller fibers with a higher surface/ volume ratio are more susceptible to degradation due to environmental effects. However, bigger fibers do not make as efficient filter medium.

25

#### Example 2:

#### Cross-linking of nylon fibers with phenolic resin and epoxy resin

In order to improve chemical resistance of fibers, chemical cross-linking of nylon fibers was attempted. Copolyamide (nylon 6, 66, 610) described earlier is mixed with phenolic resin, identified as Georgia Pacific 5137 and spun into fiber. Nylon:Phenolic Resin ratio and its melt temperature of blends are shown here;

	<u>Composition</u>	<u>Melting Temperature (F°)</u>
	Polyamide: Phenolic = 100:0	150
	Polyamide: Phenolic = 80:20	110
	Polyamide: Phenolic = 65:35	94
35	Polyamide: Phenolic = 50:50	65

We were able to produce comparable fiber from the blends. The 50:50 blend could not be cross-linked via heat as the fibrous structure was destroyed. Heating 65:35 blend below 90 degree C. for 12 hours improves the chemical resistance of the resultant fibers to resist dissolution in alcohol. Blends of polyamide with epoxy resin, such Epon 828 from Shell and Epi-Rez 510 can be used.

### **Example 3:**

#### **Surface modification though Fluoro Additive (Scotchgard®) Repellant**

Alcohol miscible Scotchgard® FC-430 and 431 from 3M Company were added to polyamide before spinning. Add-on amount was 10% of solids. Addition of Scotchgard did not hinder fiber formation. THC bench shows that Scotchgard-like high molecular weight repellant finish did not improve water resistance. Scotchgard added samples were heated at 300 F° for 10 minutes as suggested by manufacturer.

### **Example 4:**

#### **Modification with coupling agents**

Polymeric films were cast from polyamides with titanate coupling agents from Kenrich Petrochemicals, Inc. They include isopropyl triisostearoyl titanate (KR TTS), neopentyl (diallyl) oxytri (dioctyl) phosphato titanate (LICA12), neopentyl (diallyl) oxy, tri (N-ethylene diamino) ethyl zirconate (NZ44). Cast films were soaked in boiling water. Control sample without coupling agent loses its strength immediately, while coupling agent added samples maintained its form for up to ten minutes. These coupling agents added samples were spun into fiber (0.2 micron fiber).

### **Example 5:**

#### **Modification with Low Molecular Weight p-tert-butyl phenol polymer**

Oligomers of para-tert-butyl phenol, molecular weight range 400 to 1100, was purchased from Enzymol International, Columbus, Ohio. These low molecular weight polymers are soluble in low alcohols, such as ethanol, isopropanol and butanol. These polymers were added to co-polyamide described earlier and electrospun into 0.2 micron fibers without adverse consequences. Some polymers and additives hinder the

electrospinning process. Unlike the conventional phenolic resin described in Example 2, we have found that this group of polymers does not interfere with fiber forming process.

We have found that this group of additive protects fine fibers from wet environment as see in the plot. Figures 13-16 show that oligomers provide a very good protection at 140 F°, 100% humidity and the performance is not very good at 160 F°. We have added this additive between 5% and 15% of polymer used. We have found that they are equally effective protecting fibers from exposure to high humidity at 140 F°. We have also found out that performance is enhanced when the fibers are subjected to 150 C° for short period of time.

Table 1 shows the effect of temperature and time exposure of 10% add-on to polyamide fibers.

Table 1: Efficiency Retained (%) After 140 deg. F. Soak:

<u>Temperature</u>	<u>Heating Time</u>		
	<u>1 min</u>	<u>3 min</u>	<u>10 min</u>
150 C°	98.9	98.8	98.5
	98.8	98.9	98.8
130 C°	95.4	98.7	99.8
	96.7	98.6	99.6
110 C°	82.8	90.5	91.7
	86.2	90.9	85.7

This was a surprising result. We saw dramatic improvement in water resistance with this family of additives. In order to understand how this group of additive works, we have analyzed the fine fiber mat with surface analysis techniques called ESCA. 10% add-on samples shown in Table 1 were analyzed with ESCA at the University of Minnesota with the results shown in Table 2.

Table 2: Surface Composition (Polymer: Additive Ratio)

<u>Temperature</u>	<u>Heating Time</u>		
	1 min	3 min	10 min
150 C°.	40:60	40:60	50:50
130 C°.	60:40	56:44	62:82
110 C°.	63:37	64:36	59:41
No Heat	77:23		

Initially, it did not seem to make sense to find surface concentration of additive more than twice of bulk concentration. However, we believe that this can be explained by the molecular weight of the additives. Molecular weight of the additive of about 600 is much smaller than that of host fiber forming polymer. As they are smaller in size, they can move along evaporating solvent molecules. Thus, we achieve higher surface concentration of additives. Further treatment increases the surface concentration of the protective additive. However, at 10 min exposure, 150 C°, did not increase concentration. This may be an indication that mixing of two components of copolyamide and oligomer molecules is happening as long chain polymer has a time to move around. What this analysis has taught us is that proper selection of post treatment time and temperature can enhance performance, while too long exposure could have a negative influence.

We further examined the surface of these additive laden microfibers using techniques called Time of Flight SIMS. This technique involves bombarding the subject with electrons and observes what is coming from the surface. The samples without additives show organic nitrogen species are coming off upon bombardment with electron. This is an indication that polyamide species are broken off. It also shows presence of small quantity of impurities, such as sodium and silicone. Samples with additive without heat treatment (23 % additive concentration on surface) show a dominant species of t-butyl fragment, and small but unambiguous peaks observed for the polyamides. Also observed are high mass peaks with mass differences of 148 amu, corresponding to t-butyl phenol. For the sample treated at 10 min at 150 C° (50 % surface additive concentration by ESCA analysis), inspection shows dominance of t-butyl fragments and trace, if at all, of peaks for polyamide. It does not show peaks associated with whole t-butyl phenol and its polymers. It also shows a peak associated with C<sub>2</sub>H<sub>3</sub>O fragments.

The ToF SIMS analysis shows us that bare polyamide fibers will give off broken nitrogen fragment from exposed polymer chain and contaminants on the surface with ion bombardment. Additive without heat treatment shows incomplete coverage, indicating that additives do not cover portions of surface. The t-butyl oligomers are loosely organized on the surface. When ion beam hits the surface, whole molecules can come off along with labile t-butyl fragment. Additive with heat treatment promotes complete coverage on the surface. In addition, the molecules are tightly arranged so that only labile fragments such as t-butyl-, and possibly CH=CH-OH, are coming off and the whole molecules of t-butyl phenol are not coming off. ESCA and ToF SIMS look at different depths of surface. ESCA looks at deeper surface up to 100 Angstrom while ToF SIMS only looks at 10-Angstrom depth. These analyses agree.

#### Example 6:

##### Development of Surface Coated Interpolymer

Type 8 Nylon was originally developed to prepare soluble and crosslinkable resin for coating and adhesive application. This type of polymer is made by the reaction of polyamide 66 with formaldehyde and alcohol in the presence of acid. (Ref. Cairns, T.L.; Foster, H.D.; Larcher, A.W.; Schneider, A.K.; Schreiber, R.S. J. Am. Chem. Soc. 1949, 71, 651). This type of polymer can be electrospun and can be cross-linked. However, formation of fiber from this polymer is inferior to copolyamides and crosslinking can be tricky.

In order to prepare type 8 nylon, 10-gallon high-pressure reactor was charged with the following ratio:

Nylon 66 (duPont Zytel 101)	10 pounds
Methanol	15.1 pounds
Water	2.0 pounds
Formaldehyde	12.0 pounds

The reactor is then flushed with nitrogen and is heated to at least 135 C°. under pressure. When the desired temperature was reached, small quantity of acid was added as catalyst. Acidic catalysts include trifluoroacetic acid, formic acid, toluene sulfonic acid, maleic acid, maleic anhydride, phthalic acid, phthalic anhydride, phosphoric acid, citric acid

and mixtures thereof. Nafion<sup>®</sup> polymer can also be used as a catalyst. After addition of catalyst, reaction proceeds up to 30 minutes. Viscous homogeneous polymer solution is formed at this stage. After the specified reaction time, the content of the high pressure vessel is transferred to a bath containing methanol, water and base, like ammonium hydroxide or sodium hydroxide to shortstop the reaction. After the solution is sufficiently quenched, the solution is precipitated in deionized water. Fluffy granules of polymer are formed. Polymer granules are then centrifuged and vacuum dried. This polymer is soluble in, methanol, ethanol, propanol, butanol and their mixtures with water of varying proportion. They are also soluble in blends of different alcohols.

Thus formed alkoxy alkyl modified type 8 polyamide is dissolved in ethanol/ water mixture. Polymer solution is electrospun in a manner described in Barris U.S. Pat. No. 4,650,516. Polymer solution viscosity tends to increase with time. It is generally known that polymer viscosity has a great influence in determining fiber sizes. Thus, it is difficult to control the process in commercial scale, continuous production. Furthermore, under same conditions, type 8 polyamides do not form microfibers as efficiently as copolyamides. However, when the solution is prepared with addition of acidic catalyst, such as toluene sulfonic acid, maleic anhydride, trifluoro methane sulfonic acid, citric acid, ascorbic acid and the like, and fiber mats are carefully heat-treated after fiber formation, the resultant fiber has a very good chemical resistance. (Figure 13). Care must be taken during the crosslinking stage, so that one does not destroy fibrous structure.

We have found a surprising result when type 8 polyamide (polymer B) is blended with alcohol soluble copolyamides. By replacing 30 % by weight of alkoxy alkyl modified polyamide 66 with alcohol soluble copolyamide like SVP 637 or 651 (polymer A), Elvamide 8061, synergistic effects were found. Fiber formation of the blend is more efficient than either of the components alone. Soaking in ethanol and measuring filtration efficiency shows better than 98% filtration efficiency retention, THC bench testing showing comparable results with Type 8 polyamide alone. This type blend shows that we can obtain advantage of efficient fiber formation and excellent filtration characteristic of copolyamide with advantage of excellent chemical resistance of crosslinked type 8 polyamide. Alcohol soak test strongly suggests that non-crosslinkable copolyamide has participated in crosslinking to maintain 98 % of filtration efficiency.

DSC (see Figures 17-20) of blends of polymer A and B become indistinguishable from that of polymer A alone after they are heated to 250 C°. (fully crosslinked) with no distinct melt temperature. This strongly suggests that blends of polymer A and B are a fully integrated polymer by polymer B crosslinking with polymer A. This is a completely new class of polyamide.

Similarly, melt-blend poly (ethylene terephthalate) with poly(butylene terephthalate) can have similar properties. During the melt processing at temperatures higher than melt temperature of either component, ester group exchange occurs and inter polymer of PET and PBT formed. Furthermore, our crosslinking temperature is lower than either of single component. One would not have expected that such group exchange occur at this low temperature. Therefore, we believe that we found a new family of polyamide through solution blending of Type A and Type B polyamide and crosslinking at temperature lower than the melting point of either component.

When we added 10% by weight of t-butyl phenol oligomer (Additive 7) and heat treated at temperature necessary for crosslinking temperature, we have found even better results. We theorized that hydroxyl functional group of t-butyl phenol oligomers would participate in reaction with functional group of type 8 nylons. What we have found is this component system provides good fiber formation, improved resistance to high temperature and high humidity and hydrophobicity to the surface of fine fiber layers.

We have prepared samples of mixture of Polymer A and Polymer B (Sample 6A) and another sample of mixture of Polymer A, Polymer B and Additive & (Sample 6B). We then formed fiber by electrospinning process, exposed the fiber mat at 300°F for 10 minutes and evaluated the surface composition by ESCA surface analysis.

Table 3: ESCA analysis of Samples 6A and 6B.

Composition (%)		Sample 6A		Sample 6B	
5	Polymer A	30		30	
	Polymer B	70		70	
	Additive 7	0		10	
Surface Composition		W/O Heat	W/Heat	W/O Heat	W/Heat
10	Polymer A&B (%)	100	100	68.9	43.0
	Additive 7	0	0	31.1	57.0

ESCA provides information regarding surface composition, except the concentration of hydrogen. It provides information on carbon, nitrogen and oxygen. Since the Additive 7 does not contain nitrogen, we can estimate the ratio of nitrogen containing polyamides and additive that does not contain nitrogen by comparing concentration of nitrogen. Additional qualitative information is available by examining O 1s spectrum of binding energy between 535 and 527 eV. C=O bond has a binding energy at around 531 eV and C-O bond has a binding energy at 533 eV. By comparing peak heights at these two peaks, one can estimate relative concentration of polyamide with predominant C=O and additive with solely C-O groups. Polymer B has C-O linkage due to modification and upon crosslinking the concentration of C-O will decrease. ESCA confirms such reaction had indeed occurred, showing relative decrease of C-O linkage. (Figure 4 for non heat treated mixture fiber of Polymer A and Polymer B, Figure 5 for heat treated mixture fiber of Polymer A and Polymer B). When Additive 7 molecules are present on the surface, one can expect more of C-O linkage. This is indeed the case as can be seen in Figures 6 and 7. (Figure 6 for as-spun mixture fibers of Polymer A, Polymer B and Additive 7. Figure 7 for heat treated mixture fibers of Polymer A, Polymer B and Additive 7). Figure 6 shows that the concentration of C-O linkage increases for Example 7. The finding is consistent with the surface concentration based on XPS multiplex spectrum of Figures 8 through 11.

It is apparent that t-butyl oligomer molecules migrated toward the surface of the fine fibers and form hydrophobic coating of about 50 Å. Type 8 nylon has functional groups such as -CH<sub>2</sub>OH and -CH<sub>2</sub>OCH<sub>3</sub>, which we expected to react with -OH group of t-butyl phenol. Thus, we expected to see less oligomer molecules on the surface of the fibers. We have

found that our hypothesis was not correct and we found the surface of the interpolymer has a thin coating.

Samples 6A, 6B and a repeat of sample described in Section 5 have been exposed THC bench at 160°F at 100% RH. In previous section, the samples were exposed to 140°F and 100% RH. Under these conditions, t-butyl phenol protected terpolymer copolyamide from degradation. However, if the temperature is raised to 160°F and 100% RH, then the t-butyl phenol oligomer is not as good in protecting the underlying terpolymer copolyamide fibers. We have compared samples at 160°F and 100% RH.

Table 4: Retained Fine Fiber Efficiency after Exposure to 160°F and 100% RH

Sample	After 1 Hr.	After 2 Hrs.	After 3 Hrs.
Sample 6A	82.6	82.6	85.9
Sample 6B	82.4	88.4	91.6
Sample 5	10.1		

The table shows that Sample 6B helps protect exposure to high temperature and high humidity.

More striking difference shows when we exposed to droplets of water on a fiber mat. When we place a drop of DI water in the surface of Sample 6A, the water drops immediately spread across the fiber mat and they wet the substrate paper as well. On the other hand, when we place a drop of water on the surface of Sample 6B, the water drop forms a bead and did not spread on the surface of the mat. We have modified the surface of Sample 16 to be hydrophobic by addition of oligomers of p-t-butyl phenol. This type of product can be used as a water mist eliminator, as water drops will not go through the fine fiber surface layer of Sample 6B.

Samples 6A, 6B and a repeat sample of Section 5 were placed in an oven where the temperature was set at 310°F. Table shows that both Samples 6A and 6B remain intact while Sample of Section 5 was severely damaged.

Table 5: Retained Fine Fiber Efficiency after Exposure to 310°F.

	Sample	After 6 Hrs.	After 77 Hrs.
5	Sample 6A	100%	100%
	Sample 6B	100%	100%
	Sample 5	34%	33%

While addition of oligomer to Polymer A alone improved the high temperature resistance of fine fiber layer, the addition of Additive 7 has a neutral effect on the high temperature exposure.

We have clearly shown that the mixture of terpolymer copolyamide, alkoxy alkyl modified nylon 66 and oligomers of t-butyl phenol provides a superior products in helping fine fibers under severe environment with improved productivity in manufacturing over either mixture of terpolymer copolyamide and t-butyl phenol oligomer or the mixture of terpolymer copolyamide and alkoxy alkyl modified nylon 66. These two components mixture are also improvement over single component system.

#### Example 7:

##### Compatible Blend of Polyamides and Bisphenol A polymers

A new family of polymers can be prepared by oxidative coupling of phenolic ring (Pecora, A; Cyrus, W. US Patent 4,900,671(1990) and Pecora, A; Cyrus, W.; Johnson, M. US Patent 5,153,298(1992)). Of particular interest is polymer made of Bisphenol A sold by Enzymol Corp.. Soybean Peroxidase catalyzed oxidation of Bisphenol A can start from either side of two -OH groups in Bisphenol A. Unlike Bisphenol A based polycarbonate, which is linear, this type of Bisphenol A polymer forms hyperbranched polymers. Because of hyperbranched nature of this polymer, they can lower viscosity of polymer blend.

We have found that this type of Bisphenol A polymer can be solution blended with polyamides. Reported Hansen's solubility parameter for nylon is 18.6. (Page 317, Handbook of Solubility Parameters and other cohesion parameters, A. Barton ed., CRC Press, Boca Raton Florida, 1985) If one calculates solubility parameter (page 61, Handbook of Solubility Parameters), then the calculated solubility parameter is 28.0. Due to the differences in solubility parameter, one would not expect that they would be miscible with each other.

However, we found that they are quite miscible and provide unexpected properties.

50:50 blend of Bisphenol A resin of M.W. 3,000 and copolyamide was made in ethanol solution. Total concentration in solution was 10 %. Copolyamide alone would have resulted in 0.2 micron fiber diameter. Blend resulted in lofty layer of fibers around 1 micron.

5 Bisphenol A of 7,000 M.W. is not stable with copolyamide and tends to precipitate.

DSC of 50:50 blend shows lack of melting temperature. Copolyamide has melting temperature around 150 degree C and Bisphenol A resin is a glassy polymer with Tg of about 100. The blend shows lack of distinct melting. When the fiber mat is exposed to 100 degree C., the fiber mat disappears. This blend would make an excellent filter media where upper  
10 use temperature is not very high, but low-pressure drop is required. This polymer system could not be crosslinked with a reasonable manner.

#### Example 8:

##### Dual Roles of Bisphenol A Polymer As Solvent and Solid in Blend

15 A surprising feature of Bisphenol A polymer blend is that in solution form Bisphenol A polymer acts like a solvent and in solid form the polymer acts as a solid. We find dual role of Bisphenol A polymer truly unique.

The following formulation is made:

20	Alkoxy alkyl modified PA 66: Polymer B	180 g
	Bisphenol A Resin (3,000 MW): Polymer C	108 g
	Ethanol 190 Grade	827 g
	Acetone	218 g
	DI water	167 g
25	Catalyst	9.3 g

The viscosity of this blend was 32.6 centipoise by Brookfield viscometer. Total polymer concentration was be 19.2 %. Viscosity of Polymer B at 19.2% is over 200 centipoise. Viscosity of 12% polymer B alone in similar solvent is around 60 centipoise. This is a clear example that Bisphenol A resin acts like a solvent because the viscosity of the total  
30 solution was lower than expected. Resultant fiber diameter was 0.157 micron. If polymer B alone participated in fiber formation, the expected fiber size would be less than 0.1 micron. In other words, Polymer C participated in fiber formation. We do not know of any other case of such dramatic dual role of a component. After soaking the sample in ethanol, the filtration

efficiency and fiber size was measured. After alcohol soak, 85.6% of filtration efficiency was retained and the fiber size was unchanged. This indicates that Polymer C has participated in crosslinking acting like a polymer solid.

Another polymer solution was prepared in the following manner:

5	Alkoxy alkyl Modified PA66:	Polymer B	225 g
	Bisphenol A Resin (3,000 MW):	Polymer C	135 g
	Ethanol 190 Grade		778 g
	Acetone		205 g
	DI Water		157 g
10	Catalyst		11.6g

Viscosity of this blend was 90.2 centipoise. This is a very low viscosity value for 24% solid. Again, this is an indication Polymer C acts like a solvent in the solution.

However, when they are electrospun into fiber, the fiber diameter is 0.438 micron. 15% solution of Polymer B alone would have produced around 0.2-micron fibers. In final state, Polymer C contributes to enlarging fiber sizes. Again, this example illustrates that this type of branched polymer acts as a solvent in solution and acts as a solid in final state. After soaking in ethanol solution, 77.9% of filtration efficiency was retained and fiber size was unchanged.

20

#### Example 9:

##### Development of Crosslinked Polyamides/ Bisphenol A Polymer Blends

Three different samples were prepared by combining resins, alcohols and water, stirring 2 hours at 60 degree C. The solution is cooled to room temperature and catalyst was added to solution and the mixture was stirred another 15 minutes. Afterward, viscosity of solution was measured and spun into fibers.

25

The following table shows these examples:

	<u>Recipe (g)</u>	<u>Sample 9A</u>	<u>Sample 9B</u>	<u>Sample 9C</u>
	Polymer B	8.4	12.6	14.7
5	Polymer A	3.6	5.4	6.3
	Polymer C	7.2	10.8	12.6
	Ethanol 190 Grade	89.3	82.7	79.5
	Isopropanol	23.5	21.8	21.0
	DI Water	18.0	16.7	15.9
10	Catalyst	.45	0.58	0.79
	Viscosity (cP)	22.5	73.5	134.2
	Fiber Size (micron)	0.14	0.258	0.496

15           We have found out that this blend generates fibers efficiently, producing about 50 % more mass of fiber compared to Polymer A recipe. In addition, resultant polymeric microfibers produce a more chemically resistant fiber. After alcohol soak, a filter made from these fibers maintained more than 90 % filtration efficiency and unchanged fiber diameter even though inherently crosslinkable polymer is only 44% of the solid composition. This

20           three-polymer composition of co-polyamide, alkoxy alkyl modified Nylon 66 and Bisphenol A creates excellent fiber forming, chemically resistant material.

#### Example 10:

##### Alkoxy alkyl modified co-polymer of Nylon 66 and Nylon 46

25           In a 10-gallon high-pressure reactor, the following reactions were made, and resultant polymers were analyzed. After reaction temperature was reached, catalyst were added and reacted for 15 minutes. Afterward, the polymer solution was quenched, precipitated, washed and dried.

	Reactor Charge (LB)	Run 10A	Run 10B	Run 10C	Run 10D	Run 10E
	Nylon 4,6 (duPont Zytel 101)	10	5	5	5	5
	Nylon 6,6 (DSM Stanyl 300)	0	5	5	5	5
	Formaldehyde	8	10	8	10	8
5	DI Water	0.2	0.2	2	0.2	2
	Methanol	22	20	20	20	20
	Reaction Temp (C°)	140	140	140	150	150
	Tg (C°)	56.7	38.8	37.7	38.5	31.8
10	Tm (C°)	241.1	162.3	184.9	175.4	189.5
	Level of Substitution					
	Alkoxy (wt. %)	11.9	11.7	7.1	11.1	8.4
15	Methylol (wt %)	0.14	0.13	0.14	0.26	0.24

DSC of the polymer made with Nylon 46 and Nylon 66 shows broad single melt temperature, which are lower than the melting temperature of modified Nylon 46 (241 C°) or modified Nylon 66 (210 C°). This is an indication that during the reaction, both components are randomly distributed along the polymer chain. Thus, we believe that we have achieved random copolymer of Nylon 46 and Nylon 66 with alkoxy alkyl modification. These polymers are soluble in alcohols and mixtures of alcohol and water.

Property	ASTM	Nylon 6.6	Nylon 4.6
T <sub>m</sub>		265°C	295°C
Tensile Strength	D638	13,700	8,500
Elongation at Break	D638	15-80	60
Tensile Yield Strength	D638	8000-12,000	
Flexural Strength	D790	17,800	11,500
Tensile Modulus x 10 <sup>3</sup> psi	D638	230-550	250
Izod Impact ft-lb/in of notch	D256A	0.55-1.0	17
Deflection Temp Under Flexural Load 264 psi	D648	158	194

Both are highly crystalline and are not soluble in common alcohols.

### Example 11:

#### Development of Interpolymer of copolyamides and alkoxyalkyl modified Nylon 46/66 copolymer and formation of electrospun fibers

Runs 10B and 10D samples were made into fibers by methods described in above.

- 5 Alkoxy alkyl modified Nylon 46/66 (Polymer D) alone were successfully electrospun. Blending Polymer D with Polymer A brings additional benefits of more efficient fiber formation and ability to make bigger fibers without sacrificing the crosslinkability of Polymer D as can be seen in the following table:

	<u>Polymer 10B</u>		<u>Polymer 10D</u>	
	<u>Alone</u>	<u>w/30% Polymer A</u>	<u>Alone</u>	<u>w/30% Polymer A</u>
Fiber Size(micron)	0.183	0.464	0.19	0.3
Fiber Mass Ratio	1	3	1	2
15 Filtration Effi. Retention(%)	87	90	92	90

Fiber Mass Ratio is calculated by (total length of fiber times cross sectional area).

- 20 Filtration Efficiency Retention is measured soaking filter sample in ethanol. Fiber size was unchanged by alcohol soak.

### Example 12:

#### Crosslinked, Electrospun PVA

- 25 PVA powders were purchased from Aldrich Chemicals. They were dissolved either in water or 50/50 mixture of methanol and water. They were mixed with crosslinking agent and toluene sulfonic acid catalyst before electrospinning. The resulting fiber mat was crosslinked in an oven at 150°C for 10 minutes before exposing to THC bench.

	Sample 12A	Sample 12B	Sample 12C	Sample 12D
PVA				
Hydrolysis	98-99	87-89	87-89	87-89
M.W.	31,500-50,000	31,500-50,000	31,500-50,000	31,500-50,000
PVA	10	10	10	10
Conc. (%)				
Solvent	Water	Mixture	Mixture (c)	Mixture (d)
Other Polymer	None	None	Acrylic Acid	Cymel 385
Other Polymer/ PVA (%)	0	0	30	30
% Fiber	0 (a)	0 (a,b)	95 (b)	20 (b)
Retained THC, 1 hr.				
% Fiber			90 (a)	
Retained THC, 3 hr.				

(a): Temperature 160°F, 100% humidity

5 (b): Temperature 140°F, 100% humidity

(c): Molecular Weight 2000

(d): Melamine formaldehyde resin from Cytec

### **Example 13**

15

20

A conventional cellulose air filter media was used as the substrate. This substrate had a basis weight of 67 pounds per 3000 square feet, a Frazier permeability of 16 feet per minute at 0.5 inches of water pressure drop, a thickness of 0.012 inches, and a LEFS efficiency of 41.6%. A fine fiber layer of Example 1 was added to the surface using the process described with a nominal fiber diameter of 0.2 microns. The resulting composite had a LEFS efficiency of 63.7%. After exposure to 140F air at 100% relative humidity for 1 hour the substrate only sample was allowed to cool and dry, it then had a LEFS efficiency of 36.5%. After exposure to 140F air at 100% relative humidity for 1 hour the composite sample was allowed to cool and dry, it then had a LEFS efficiency of 39.7%. Using the mathematical formulas described, the fine fiber layer efficiency retained after 1 hour of exposure was 13%, the number of effective fine fibers retained was 11%.

#### **Example 14**

A conventional cellulose air filter media was used as the substrate. This substrate had a basis weight of 67 pounds per 3000 square feet , a Frazier permeability of 16 feet per minute at 0.5 inches of water pressure drop, a thickness of 0.012 inches, and a LEFS efficiency of 41.6% . A fine fiber layer of Example 5 was added to the surface using the process described with a nominal fiber diameter of 0.2 microns. The resulting composite had a LEFS efficiency of 96.0%. After exposure to 160F air at 100% relative humidity for 3 hours the substrate only sample was allowed to cool and dry, it then had a LEFS efficiency of 35.3%. After exposure to 160F air at 100% relative humidity for 3 hours the composite sample was allowed to cool and dry, it then had a LEFS efficiency of 68.0%. Using the mathematical formulas described, the fine fiber layer efficiency retained after 3 hours of exposure was 58%, the number of effective fine fibers retained was 29%.

#### **Example 15**

A conventional cellulose air filter media was used as the substrate. This substrate had a basis weight of 67 pounds per 3000 square feet , a Frazier permeability of 16 feet per minute at 0.5 inches of water pressure drop, a thickness of 0.012 inches, and a LEFS efficiency of 41.6% . A fine fiber layer of a blend of Polymer A and Polymer B as described in Example 6 was added to the surface using the process described with a nominal fiber diameter of 0.2 microns. The resulting composite had a LEFS efficiency of 92.9%. After exposure to 160F air at 100% relative humidity for 3 hours the substrate only sample was allowed to cool and dry, it then had a LEFS efficiency of 35.3%. After exposure to 160F air at 100% relative humidity for 3 hours the composite sample was allowed to cool and dry, it then had a LEFS efficiency of 86.0%. Using the mathematical formulas described, the fine fiber layer efficiency retained after 3 hours of exposure was 96%, the number of effective fine fibers retained was 89%.

#### **Example 16**

A conventional cellulose air filter media was used as the substrate. This substrate had a basis weight of 67 pounds per 3000 square feet , a Frazier permeability of 16 feet per minute at 0.5 inches of water pressure drop, a thickness of 0.012 inches, and a LEFS

efficiency of 41.6% . A fine fiber layer of Polymer A, Polymer B, t-butyl phenol oligomer as described in Example 6 was added to the surface using the process described with a nominal fiber diameter of 0.2 microns. The resulting composite had a LEFS efficiency of 90.4%. After exposure to 160F air at 100% relative humidity for 3 hours the substrate only sample  
5 was allowed to cool and dry, it then had a LEFS efficiency of 35.3%. After exposure to 160F air at 100% relative humidity for 3 hours the composite sample was allowed to cool and dry, it then had a LEFS efficiency of 87.3%. Using the mathematical formulas described, the fine fiber layer efficiency retained after 3 hours of exposure was 97%, the number of effective fine fibers retained was 92%.

10

#### Example 17

A conventional cellulose air filter media was used as the substrate. This substrate had a basis weight of 67 pounds per 3000 square feet , a Frazier permeability of 16 feet per minute at 0.5 inches of water pressure drop, a thickness of 0.012 inches, and a LEFS efficiency of  
15 41.6% . A fine fiber layer of crosslinked PVA with polyacrylic acid of Example 12 was added to the surface using the process described with a nominal fiber diameter of 0.2 microns. The resulting composite had a LEFS efficiency of 92.9%. After exposure to 160F air at 100% relative humidity for 2 hours the substrate only sample was allowed to cool and dry, it then had a LEFS efficiency of 35.3%. After exposure to 160F air at 100% relative  
20 humidity for 2 hours the composite sample was allowed to cool and dry, it then had a LEFS efficiency of 83.1%. Using the mathematical formulas described, the fine fiber layer efficiency retained after 2 hours of exposure was 89%, the number of effective fine fibers retained was 76%.

### Example 18

The following filter medias have been made with the methods described in Example 1-17.

#### Filter Media Examples

Substrate	Substrate perm (Frazier)	Substrate Basis wt (lbs/3000 sq ft)	Substrate Thickness (in)	Substrate Eff (LEFS)	Composite Eff (LEFS)
Single fine fiber layer on single substrate (flow either direction through media	(+/- 10%)	(+/- 10%)	(+/- 25%)	(+/- 5%)	(+/- 5%)
Cellulose air filter media	58	67	0.012	11%	50%
Cellulose air filter media	16	67	0.012	43%	58%
Cellulose air filter media	58	67	0.012	11%	65%
Cellulose air filter media	16	67	0.012	43%	70%
Cellulose air filter media	22	52	0.010	17%	70%
Cellulose air filter media	16	67	0.012	43%	72%
Cellulose/synthetic blend with moisture resistant resin	14	70	0.012	30%	70%
Flame retardant cellulose air filter media	17	77	0.012	31%	58%

Filter Media Examples (Continued)

Substrate	Substrate perm (Frazier)	Substrate Basis wt (lbs/3000 sq ft)	Substrate Thickness (in)	Substrate Eff (LEFS)	Composite Eff (LEFS)
Flame retardant cellulose air filter media	17	77	0.012	31%	72%
Flame retardant synthetic air filter media	27	83	0.012		77%
Spunbond Remay (polyester)	1200	15	0.007	5%	55%
Synthetic/cellulose air filter media	260	76	0.015	6%	17%
Synthetic/glass air filter media	31	70	0.012	55%	77%
Synthetic/glass air filter media	31	70	0.012	50%	90%

Filter Media Examples (Continued)

Substrate	Substrate perm (Frazier)	Substrate Basis wt (lbs/3000 sq ft)	Substrate Thickness (in)	Substrate Eff (LEFS)	Composite Eff (LEFS)
Synthetic (Lutrador-polyester)	300	25	0.008	3%	65%
Synthetic (Lutrador-polyester)			0.016		90%

Media has been used flat, corrugated, pleated, corrugated and pleated, in flatsheets, pleated flat panels, pleated round filters, 5 and Zee filters.

## TEST METHODS

### Hot Water Soak Test

Using filtration efficiency as the measure of the number of fine fibers effectively and functionally retained in structure has a number of advantages over other possible methods such as SEM evaluation.

- the filtration measure evaluates several square inches of media yielding a better average than the tiny area seen in SEM photomicrographs (usually less than 0.0001 square inch

- the filtration measurement quantifies the number of fibers remaining functional in the structure. Those fibers that remain, but are clumped together or otherwise existing in an altered structure are only included by their measured effectiveness and functionality.

Nevertheless, in fibrous structures where the filtration efficiency is not easily measured, other methods can be used to measure the percent of fiber remaining and evaluated against the 50% retention criteria.

Description: This test is an accelerated indicator of filter media moisture resistance. The test uses the LEFS test bench to measure filter media performance changes upon immersion in water. Water temperature is a critical parameter and is chosen based on the survivability history of the media under investigation, the desire to minimize the test time and the ability of the test to discriminate between media types. Typical water temperatures are 70°F, 140°F or 160°F.

#### Procedure:

A 4" diameter sample is cut from the media. Particle capture efficiency of the test specimen is calculated using 0.8µm latex spheres as a test challenge contaminant in the LEFS (for a description of the LEFS test, see ASTM Standard F1215-89) bench operating at 20 FPM. The sample is then submerged in (typically 140°F) distilled water for 5 minutes. The sample is then placed on a drying rack and dried at room temperature (typically overnight). Once it is dry the sample is then retested for efficiency on the

LEFS bench using the same conditions for the initial calculation.

The previous steps are repeated for the fine fiber supporting substrate without fine fiber.

- 5 From the above information one can calculate the efficiency component due only to the fine fiber and the resulting loss in efficiency due to water damage. Once the loss in efficiency due to the fine fiber is determined one can calculate the amount of efficiency retained.

10 Calculations:

Fine fiber layer efficiency:  $E_i$  = Initial Composite Efficiency;  
 $E_s$  = Initial Substrate Efficiency;  
 $F_e$  = Fine Fiber Layer  
 $F_e = 1 - \text{EXP}(\text{Ln}(1 - E_i) - \text{Ln}(1 - E_s))$

15

Fine fiber layer efficiency retained:  $F_i$  = Initial fine fiber layer efficiency;  
 $F_x$  = Post soak fine fiber layer efficiency;  
 $F_r$  = Fine fiber retained

20

$$F_r = F_x / F_i$$

The percentage of the fine fibers retained with effective functionality can also be calculated by:

25

$$\% = \log(1 - F_x) / \log(1 - F_i)$$

Pass/Fail Criteria: >50% efficiency retention

In most industrial pulse cleaning filter applications the filter would perform adequately if at least 50% of the fine fiber efficiency is retained.

30

### THC Bench (Temperature, Humidity)

Description: The purpose of this bench is to evaluate fine fiber media resistance to the affects of elevated temperature and high humidity under dynamic flow conditions. The test is intended to simulate extreme operating conditions of either an industrial filtration application, gas turbine inlet application, or heavy duty engine air intake environments. Samples are taken out, dried and LEFS tested at intervals. This system is mostly used to simulate hot humid conditions but can also be used to simulate hot/cold dry situations.

Temperature -31 to 390°F

Humidity 0 to 100% RH (Max temp for 100% RH is 160°F and max continuous duration at this condition is 16 hours)

Flow Rate 1 to 35 FPM

Procedure:

A 4" diameter sample is cut from the media.

Particle capture efficiency of the test specimen is calculated using 0.8µm latex spheres as a test challenge contaminant in the LEFS bench operating at 20 FPM.

The sample is then inserted into the THC media chuck.

Test times can be from minutes to days depending on testing conditions.

The sample is then placed on a drying rack and dried at room temperature (typically overnight). Once it is dry the sample is then retested for efficiency on the LEFS bench using the same conditions for the initial calculation.

The previous steps are repeated for the fine fiber supporting substrate without fine fiber.

From the above information one can calculate the efficiency component due only to the fine fiber and the resulting loss in efficiency due to alcohol damage.

Once the loss in efficiency due to the fine fiber is determined one can calculate the amount of efficiency retained.

Pass/Fail Criteria: >50% efficiency retention

In most industrial pulse cleaning filter applications the filter would perform adequately if

at least 50% of the fine fiber efficiency is retained.

#### Alcohol (Ethanol) Soak Test

Description: The test uses the LEFS test bench to measure filter media performance  
5 changes upon immersion in room temperature ethanol.

#### Procedure:

A 4" diameter sample is cut from the media. Particle capture efficiency of the test  
specimen is calculated using 0.8 $\mu$ m latex spheres as a test challenge contaminant in the  
10 LEFS bench operating at 20 FPM. The sample is then submerged in alcohol for 1  
minute.

The sample is then placed on a drying rack and dried at room temperature (typically  
overnight). Once it is dry the sample is then retested for efficiency on the LEFS bench  
15 using the same conditions for the initial calculation. The previous steps are repeated for  
the fine fiber supporting substrate without fine fiber. From the above information one can  
calculate the efficiency component due only to the fine fiber and the resulting loss in  
efficiency due to alcohol damage. Once the loss in efficiency due to the fine fiber is  
determined one can calculate the amount of efficiency retained.

20

Pass/Fail Criteria: >50% efficiency retention.

The above specification, examples and data provide an explanation of the  
invention. However, many variations and embodiments can be made to the disclosed  
25 invention. The invention is embodied in the claims herein after appended.
